MORE PAGES IN BEEBUG

This is the first regular issue of BEEBUG with an extra four pages. We hope that in the next few months that this will enable us to include more reviews and other information as well as some extra programs and other features. We shall be taking advantage of the extra pages next month to add a Christmas flavour to the magazine.

DNFS ROM FROM ACORN

The DNFS ROM, supplied as part of Acorn's second processor systems, is now available separately for around £20.60 inc. VAT. This provides later, improved versions of the Disc and Network Filing Systems. The chip is accompanied by a 10 page booklet. The Acorn reference number is ANB21.

NOTICE BOARD NOTICE BOARD NOTICE BOARD NOTICE BO

NEW RELEASES FROM BEEBUGSOFT

You should receive a copy of our new software brochure with this magazine mailing. As you will see, we have considerably expanded the range of our software, and have upgraded a number of our current titles. For example Masterfile II allows very flexible print options, and can even print documents from Wordwise or View, inserting specified data from Masterfile - e.g. insert the name, address and other particulars into circulars etc. Exmon II incorporates a full screen editor, and dual screen facilities, and we have a ROM based version of Spellcheck which runs up to 10 times faster than the disc based version. Upgrades for all these products are available at 50% discount on trade in of previous versions.

Sleuth is a totally new ROM offering dual screen single step debugging in Basic. Our Music Extension ROM is also worth close examination, and we are now offering our own brand of full specification discs which are fully tested and guaranteed, and supplied in a free case in quantities of 10, 25 and 30.

We are now taking Access and Barclaycard orders on all products - ring Penn (0494810) 6666 (multi-lines, 24 hour service). If you are taking a member's discount it is essential to quote your membership number.

In expanding our range of products we have regretfully had to phase out our software club offers. See this month's supplement for stock clearance price cuts.

PRINTMASTER ROM UPDATE

The STAR compatible version of Printmaster is now available at the same price as the existing Epson version. The new release will work with STAR printer models DELTA, DP, GEMINI and RADIX.

Computer Concepts have also stated that they believe the Epson version of Printmaster will work with the following compatible printers: KAGA TAXAN, CANON, MANNESMAN TALLY MT80.

HINT WINNERS

This month F.Duerden is the winner of the £10 prize, and S.R.Linton and D.Long both win £5 prizes. We are always please to receive your latest hints for the magazine.

MAGAZINE CASSETTE/DISC

This month we have included one extra program on the magazine cassette/disc. This is a copy of the PACK program by David Tall first published in BEEBUG Vol.1 No.9, and is intended to complement the Cross Reference program included in this month's magazine. The PACK program can be used to remove unnecessary spaces and comments from programs to save space.

ACORNSOFT ISO-PASCAL

Reviewed by Matthew Rapier and Paul Spurgeon

At last a full implementation of Pascal is available for the BBC micro. We report on ISO-Pascal, a major new programming language system from Acornsoft, due to be launched in mid November.

Product:	ISO-PASCAL
Supplier:	Acornsoft
Price:	£69.00 inc VAT.

ISO-PASCAL from Acornsoft is a full implementation of the Pascal language to the latest ISO standard. Pascal is very popular as a teaching language. However, it is not just limited to use in Universities and Colleges, but is often used for systems programming and other applications on all manner of computer systems.

Compared to S-Pascal and the HCCS Pascal, this is surely a superb system. At £69 it is one of the cheapest full language systems available for the Beeb as an alternative to Basic.

A BRIEF EXPLANATION OF PASCAL

Pascal is an example of what is termed a 'block structured' language. For those unfamiliar with block structured languages it is worthwhile giving a brief explanation of Pascal. It is impossible here to describe all the features of the language, and for further information you should consult some of the many books that explain the language more fully.

Pascal was devised by Niklaus Wirth at the Technological University of Zurich to embody the best principles of program structure and design. Pascal is a well defined language with a recognised standard (see Jensen and Wirth, "Pascal User Manual and Report", Springer -Verlag, New York 1975), which has deservedly established a world wide reputation.

Pascal programs are entered and modified using a text editor (akin to Wordwise or View on the BBC micro), and without line numbers. At this stage a Pascal program is simply a standard text file and this allows instructions to be laid out in a way which emphasizes the structure of the program

as shown in the example:

```

WHILE p > start DO
  BEGIN
    q:=start+1;
    p:=p-1;
    WHILE q < fin DO
      BEGIN
        q:=q+1;
        IF NOT costfixed THEN
          IF cost+max<total THEN
            BEGIN
              total:=cost+max; min:=w
            END
          END
        END
      END
    END
  END

```

Once the text of the Pascal program has been entered and saved on disc, it can then be compiled to machine code or similar using a Pascal compiler. It is this 'object code' file which is then executed to run the program.

One important feature of Pascal is the way in which 'compound' statements can be constructed consisting of simple statements enclosed between 'BEGIN' and 'END'. A compound statement can be used anywhere in the program in place of a simple statement. This leads to the nested block structure so typical of Pascal and encourages a well structured approach to the writing of Pascal programs. This is helped by a comprehensive set of structured control statements including not only the REPEAT-UNTIL that is part of BBC Basic, but also a WHILE-DO and most useful, a CASE statement which provides for multiple branching usually handled by the IF-THEN-ELSE or ON-GOTO type of construction in Basic.

Procedures and functions also feature strongly in Pascal, though the Pascal versions are both more powerful and flexible than in BBC Basic. They can be thought of in simple terms as a block with a name. The block of the procedure can refer to previously defined procedures and to itself,

allowing recursion. The use of parameters and local variables ensures that both functions and procedures can be written quite independently of each other and the main program.

Another characteristic of Pascal is its insistence that the data type of every variable be declared before use. Not only that, but Pascal also allows you to define your own data types. In a procedure definition the type of each parameter is explicitly stated and you can only pass variables of the correct type to that procedure. This strong data typing helps to structure the program and often highlights potential errors caused by the mis-match of data types at an early stage of program development. The option to define your own data types also allows complex data structures to be introduced into a program with minimal difficulty.

ACORNSOFT ISO-PASCAL

ISO-Pascal is supplied on two 16K ROMs for standard BBC machines and on disc for use with the 6502 second processor. One ROM contains a machine code interpreter, to execute the intermediate code generated by the compiler, and also the editor and other Pascal system commands. The other ROM contains the compiler but this still needs the interpreter to run. Pascal programs are standard ASCII text files which are then compiled, not directly into machine code, but into an intermediate code (called BL code). This is then interpreted by the BL interpreter in ROM. The Pascal compiler is itself in BL code (presumably compiled from Pascal) which is why the compiler needs the interpreter.

Switching between the two ROMs is automatically controlled by the Pascal interpreter ROM. The system can be used with any filing system, but to use full error reporting a random access system like DFS or Econet is necessary. The system will work with cassette files but developing large programs in this way would be very tedious.

THE EDITOR

A text editor is provided as part of the main ROM for the creation and editing of Pascal programs, though other text editors such as View or

Wordwise could equally well be used. The supplied editor is quite powerful with screen editing using the cursor and function keys, and includes a very flexible search and replace facility. You can search not only for alpha-numeric (including spaces), but also for ranges of characters, not ranges of characters and so on, making this a very useful and powerful feature.

THE COMPILER

The ROM based compiler will compile a program from either a disc file or from the current memory file created by the editor. The intermediate code file in turn can be sent either to disc or stored in memory. This provides a fast development environment for small programs as both source and object code may be kept together in memory. The disc based compiler for the 6502 second processor system does not have this facility, and can only compile from and to disc. Compiling a Pascal source program provides a line numbered listing of the program on the screen (which can be turned off) as compilation proceeds.

The single pass compiler produces runnable intermediate code if no errors are encountered. If an error is found then the compiler pauses, giving an error code, and if an error file is available on disc, a descriptive message. It also identifies the line in error by giving a line number, and also points to the approximate position of the error. The editor is able to search for and locate a specified line number in the Pascal source program (remember that this does not explicitly include line numbers), a feature not usually available in word processors. Not only did the compiler seem to run slowly (with or without the listing being displayed on the screen), but error messages took a surprisingly long time for the compiler to fetch from disc.

The disc version of the compiler implements the full ISO specification to level 1a, while the ROM version is to the lower level 0b (thus no support for conformant arrays, and packing has no effect on strings).

THE EXTENSIONS

Acornsoft have added many extensions

to their ISO-Pascal to allow access to the BBC micro's input and output routines. These are, of course, non-standard (in Pascal), and mostly mimic the operation of BBC Basic functions (including MODE, VDU, PLOT, POINT, SOUND, ENVELOPE, OSCLI, ADVAL, INKEY, TIME, and SETTIME). Other useful extensions provide for numeric/string conversion, the use of external file names, dynamic storage management and machine code calls. The latter allow other operating system routines to be called quite easily, but calling your own machine code is more complicated, though it is all explained in the manual with examples. Although these extensions make a useful addition to the language, they are not part of the accepted standard for Pascal.

HOW WELL DOES THE SYSTEM WORK?

Our impression was that the speed of execution of the compiled code was not always as fast as expected. In some examples that we tried, Basic was very slightly faster than Pascal. Run time error reporting is somewhat cryptic, and there are no extensions allowing for error trapping within a program. A simple trace facility can be enabled which prints out line numbers and procedure names as they are executed. Although it is fairly simple to write comprehensive debugging code into your program, it is much easier if the system does it all for you.

DOCUMENTATION

The system is delivered with a substantial manual, and the book "Pascal from BASIC" by P.J.Brown. The manual contains chapters on the editor, compilation, compiler options, language extensions, memory organisation, internal representations, machine code linking and various appendices. We were confused by the manual, with its large section devoted to the editor right at the start, and the chapter on using the compiler is spoilt by continual reference to memory organisation (high water mark etc.). Apart from this the manual is comprehensive and detailed in the information it provides.

THE DISADVANTAGES

There are two drawbacks to this Pascal system. There is firstly no provision for segmenting a large program into separately compiled

modules. While not standard Pascal, it is generally acknowledged that it is good practice to decompose a program into relatively independent and self-contained modules. Thus, for example, it would be useful to write a module implementing graphics calls to the BBC's operating system. A sample program showing how procedures such as `move(x,y)` and `draw(x,y)` may be written is provided, but it is impossible to compile this as a separate library module. The best that can be done is to include text files within the Pascal source program, chaining files together and creating one monolithic program, all of which has to be compiled everytime. Quite large programs can be compiled in this way.

Secondly, as already described, ISO-Pascal compiles to intermediate BL code, which can be saved to tape or disc. This code can only be executed by using the interpreter ROM, or (with a second processor) by using the disc based run-time system. There is no way of producing a compiled program that can then be run by other users, unless they buy ISO-Pascal as well. It may be that, as with BCPL, Acornsoft will produce a stand-alone package for Pascal.

THE GOOD POINTS

The system has an excellent text editor which is ideal for program development, and the compiler has good error reporting facilities which pin-point errors, at least as far as syntax is concerned. The extensions allow simple use of all the BBC micro's facilities without resorting to any complicated programming techniques. Overall, Acornsoft have achieved a notable success in implementing a full version of Pascal on the BBC micro, notwithstanding the criticisms above, and at the reasonable price of £69 for the complete ISO-Pascal system.

IN CONCLUSION

At present the main interest in this product is likely to be from lecturers and teachers seeking to use Pascal to teach computer programming, and from individuals who are interested in programming in this powerful language. For all of these, Acornsoft's ISO-Pascal provides a major new language for the BBC micro.

ELITE - AN OUTSTANDING NEW GAME FROM ACORNSOFT

Reviewed by David Fell

Name : Elite
Supplier : Acornsoft
Price : Tape £14.95 inc. VAT
Disc £17.65 inc. VAT
Rating : *****

"Acornsoft Elite is the first in a new generation of 3-D space games featuring interstellar travel in a distant cluster of galaxies..." said the advertising. Thoughts of an over-hyped third rate nightmare started to loom close as, with a degree of trepidation, I loaded Elite. That was just over a week ago, and I'm now convinced that Acornsoft have just released the best game ever for the Beeb.

Elite combines the elements of a number of classical games to produce a superb three dimensional graphical trading game of skill and absolute addiction, that squeezes every ounce of performance out of the Beeb. Let me explain this further; Elite combines together a three dimensional fast action combat game, a 'Monopoly' like trading game and various aspects of an adventure style exploration game. Elite takes its name from the overall goal of the game, which is to achieve a rating of Elite (the highest accolade available which, as yet, has not been reached by any mortal). To achieve this you need to be a successful space trader (to purchase the necessary weapons) and to achieve a high level of flying and combat skills (your rating is based upon the latter, and your survival is dependent upon both).

In Elite you pilot a Cobra MK3 space ship equipped with normal and hyperspatial drives. Combat, normal flight and docking are all performed in real time, with some stunning graphics achieving an amazing impression of realism. Docking at an orbiting space station is essential if you are to be able to trade. The trading itself is quite complex due to the sheer quantity of information involved: 2000 planets selling 17 different items; political situation; planetary produce, etc. If all this sounds too dull you can always give up the life of the honest trader and become a bounty hunter or space pirate, but this involves living life dangerously.

Combat takes a while to master, and requires sheer determination and three dimensional perception to survive. Your armoury, apart from three missiles and a small laser, will depend upon accruing money from trading. For a real demonstration of combat, go to your nearest dealer, and he should have an Elite demonstration disc. As a warning, it is said that there are spaceships 'out there' that no one has ever seen!

CONCLUSION

Elite is undoubtedly a masterpiece of programming that I would recommend anyone who has a Beeb to purchase as soon as possible. Even now, just a week after it's launch, Elite has already firmly established itself as a cult game for the Beeb that seems to create its own self perpetuating fame. There is a monthly competition for players of Elite, and full details are included with the game.

AUTO—KEYWORD GENERATOR (16k)

by John Bower

Many microcomputers, including the Electron for example, allow you to enter Basic keywords with just a few key strokes directly from the keyboard. John Bower describes a short utility to add this most useful feature to the BBC micro, to save both time and effort when typing programs into your Beeb.

The purpose of this program is to allow the user to type in a whole keyword with ease and speed. Wouldn't it be nice to be able to type in the keyword ENVELOPE by pressing only three keys instead of eight, or to type in ENDPROC with just two keys instead of seven? This utility will allow you to do not only that, but will allow you to type in up to 52 Basic keywords with a maximum of 3 key presses each time.

Q	W	E	R	T	Y	U	I	O	P
LEFTS	RUN	ENDPR.	REP.	THEN	DRAN	UNT.	INPUT	MOVE	PRINT
RIGHTS	RND	ENV.	READ	ELSE	POINT	TRUE	DIM	PLOT	PROC
A	S	D	F	G	H	J	K	L	
AUTO	SOUND	DEF	FOR	DOOL	LOCAL	TABC	INKEY	LIST	
NORMAL	SAVE	DATA	FALSE	GET	GETS	TIME	INKEYS	LOAD	
Z	X	C	V	B	N	M			
DIV	STRS	COLOUR	USR	CHR#	NEXT	MODE			
MOD	STRINGS	CH.	VAL	CLS	NEW	HDS			
BASIC KEYWORDS									

Using this program you can enter any of the 52 Basic keywords using either two or three key strokes in each case. The first 26 keywords are generated by pressing Tab followed by one of the 26 alphabetic keys, and the other 26 by using Ctrl/Tab together first. The keywords generated in this way are shown in the diagram - those using Tab alone at the top and those using Ctrl/Tab at the bottom of each pair. Even if you don't use all 52 keywords generated in this way, you may still find some of the Tab combinations particularly useful and convenient. You can also decide which 52 keywords you want to include. You may also find it helpful to copy the keyword diagram and place it above the function keys of your machine for reference.

To use the program, just type it in and save it on cassette or disc (you can omit all the assembler comments if you wish - that is text following '\'). If you are using a cassette system you will need to change the address for the location of the machine code. This is at line 110 where &A00 should be changed to &D00. A further change is required to allow this program to run properly using Basic I. The information is contained in the program as a comment at line 360, and involves changing the first instruction on line 370 from LDA #&74 (for Basic II) to LDA #&70 (for Basic I). This is because the keyword look-up table starts in a different place.

Once saved you may then run the program and test it out. To do this just press the Tab key once, and then press the 'A' key. You should now see the keyword AUTO appear on the screen. Now press Tab followed by all the other keys between A and Z to check that they all work. If some do not give the expected results, check line 600 to make sure that the values of the tokens are correct.

Next you can test if the second set of keywords work. To do this hold down the 'CTRL' key, and at the same time press 'TAB' (represented as Ctrl/Tab). Now release both keys and press a key between A and Z. You should now get more keywords, but different to those before.

If they all work (corresponding to the diagram), you can customise the program to suit your own needs. You can do this by changing lines 600, 610, 630 and 640. If for example you wish to substitute the keyword OPENOUT for GET, you can do this by finding the token for OPENOUT (&AE) from the User Guide (page 483) and putting that in place of

the token for GET (&A5) in line 640. It would also be prudent to replace the keyword GET by OPENOUT in the REM statement at line 630. The REM statements at lines 600 and 630 serve as reference guides to the current token settings in lines 610 and 640.

Once you are satisfied with the keywords that you have set up, then you can save the machine code by typing:

```
*SAVE KEYWORD A00 AFF
```

and re-run the program by typing:

```
*RUN KEYWORD
```

Cassette users should save their code by typing:

```
*SAVE KEYWORD D00 DFF.
```

You can, if you wish, use any name you choose rather than KEYWORD. To disable the effect at any time, type in the command *FX13,4 and to re-enable the code type *FX14,4. If you press Break you can restart the code by typing CALL &A00 (or CALL &D00 on cassette).

```

THE MIDLAND HOME BANKING EXPERIMENT

by Peter Rochford

Homebanking, using a specially adapted television set or a microcomputer, has been talked about for many years. The rapid increase in interest and ownership of low-cost microcomputers has now made this a reality for some. Peter Rochford describes his own experiences with this new service using a BBC micro.

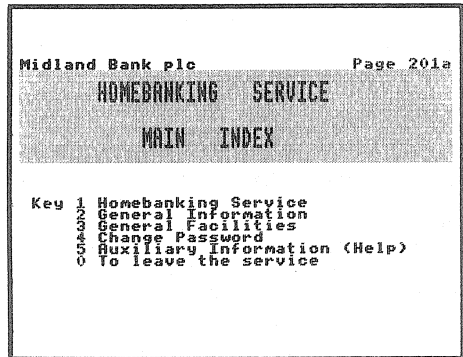

Some six months ago the Midland Bank quietly launched an experimental homebanking service for its customers. The Midland is the first of the 'big four' major banks to show any practical interest in electronic banking at the domestic user level.

The experiment was originally set to run for one year with a view to it being extended if proved successful. Those like myself, who applied to participate in the experiment, were sent a letter outlining how the system would work and details of what equipment (which includes a BBC micro with suitable Prestel type modem) would be needed by the user. During the experimental stage, no charge would be made in return for the feedback obtained from users and the resultant experience gained by the Midland Bank.

Once accepted and registered, a user is sent a rather impressive folder containing the phone numbers relevant to the system and an instruction manual. The manual is really excellent, providing easy step-by-step guides to logging on and accessing the many services available. Included in the manual are numerous facsimile screen displays and examples to help you find your way round the system.

Even at this experimental stage, the facilities and information provided are remarkably comprehensive. Obviously you can check the balance of your account(s) and look at your current or previous statement. What really impresses though, is the way in which you can use the system to interrogate your account to find individual details quickly and simply.

For example, debits can be found without having to scan through the entries of all the pages of your

statement. Instead, you can tell the system the number of the cheque you are looking for, or the value of the cheque, and it will find it for you, assuming of course that it has been entered in your account. As an alternative, you can enter start and end cheque numbers and all cheques between and including these numbers will then be displayed. You are also notified of the numbers of cheques that have not yet been cleared.

Credits can be searched for by just asking the system to search for a credit of a specific value. All credits which correspond to this value will then be displayed.

If you use a lot of standing orders homebanking is definitely for you. You can obtain a list of all your current standing orders and then go on to ask for a detailed look at any one you choose, or indeed all of them. You are given the name of the beneficiary, the bank and account into which it is paid, the frequency of payments, value of payments, when the next payment is due, and other details.

As well as examining your accounts, a recently added facility allows you to

transfer funds between your accounts on-screen. There is a set limit to the amount you can transfer in any one day and a limit to the number of transfers you can effect in one day.

Apart from the details of your account, there are a whole host of information services at your disposal on such subjects as foreign currency, interest rates, exchange rates, autobanks, personal loans etc. You may also order a new cheque book or statement and any of the currently available literature on bank services.

A mailbox is provided for sending messages to other users of the system and a noticeboard where the bank provides details of changes to the services provided.

Because of the security aspect, logging-on to the Midland Bank computer does mean remembering several codes. Once you have dialled up the computer and obtained the welcome page on screen, you are asked to enter your user number. This is a permanently allocated 6 digit number which you can divulge to other users on the system allowing them to contact you by mailbox. Next you enter a password which is not shown on screen as you type it in. Finally, before entering the system, you have to enter your customer identity. This is another password, but unlike the first, can be of variable length between four and ten characters. Both the password and customer identity can be changed on-screen as and when you wish whilst connected to the system.

Having entered all the correct codes you then gain access to the system. You are now presented with the main menu page, but to obtain access to your accounts you must type in the relevant account numbers.

Should you make a mess of typing in any of the codes, you are allowed just two further attempts before the system will disconnect you. Further attempts by re-dialling and trying to log on, even with the correct codes, will be fruitless. Access can only be restored by writing to the homebanking unit who will also re-notify you of your codes.

Midland Bank plc

HOME BANKING SERVICE

Balance Enquiries

- Key 1 Balance of nominated account
- 2 Balances of all your registered accounts
- 5 Homebanking Index
- 6 Main Index
- 0 To leave the service

In general, using the system is quite simple. There are lots of menus to guide you and in most cases it requires only a single key press to obtain the service you want. It is virtually impossible to 'get lost' in the system as there is always the facility to jump back to a menu from any page. The screen displays are very well laid out and plenty of use is made of colour to highlight various features.

To aid you in finding out about everything on offer, there is a 'rolling demonstration' that takes you through most of the services available, you just sit back and watch. This is a very helpful, not to mention intriguing facility. However, it takes quite a while so beware the cost to your telephone bill.

At present, there are certain restrictions on the system out of normal banking hours. This amounts to preventing you searching your account for credits and debits and obtaining detailed information on standing orders. This is quite significant as your telephone charges are higher during the day and you do not have the convenience of 24 hours a day full service which should surely be one of the main benefits of any homebanking system. Your balance and latest statement are always available, as are the general information and ordering services.

To use the service you must be a Midland Bank customer. Apart from that qualification, you will need your Beeb, a 1200/75 baud modem and Prestel

type software. Although the Midland homebanking uses Prestel standards it doesn't utilise Prestel to relay the information to you. Instead it uses a mini-computer, linked to the two bank mainframes, to provide a private Viewdata system. The advantage is that you don't have to be a Prestel subscriber to use the service, but the bad news is that the mini-computer is on a London number only at present. Those outside the capital may find the phone costs prohibitive. The Midland has not yet hinted how a fully fledged system would operate on a nationwide basis, perhaps they will eventually utilise Prestel.

My own personal feelings after using homebanking for six months are of great enthusiasm. I have found it well worth the cost of the phone calls and it has enabled me (much to my bank manager's joy!) to manage my account much better. How much benefit you derive from using homebanking will depend on how much use you normally make of your bank account. Businesses that need to keep close tabs on their finances I am sure will find it indispensable.

03 Homebanking Index

If the full range of services can be made available 24 hours a day and extended to cover more transactions, such as paying bills, obtaining loans etc, then homebanking will become a most useful facility for many people. Even so, the cost of the service is bound to be a significant factor as far as home users are concerned.

At the time of writing this article (July 84), the Midland Bank homebanking unit have indicated that the experiment is to be extended for a further year and that there is spare capacity on the system for anyone wishing to become a user of the service. For further details and to check availability at present, you should contact them at the address shown below.

HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

NUMBER OF CHARACTERS PER LINE

If you wish to calculate screen width dependent on the current mode, then the following formula will enable you to do this (C% will hold the number of characters on exit, and M% holds the mode number on entry):

```
IF M% < 6 C% = 2^(2 - (M% MOD 3)) * 20 ELSE C% = 40
```

DISC TIPS - Peter Chambers

When using either DNFS or Watford DFS with a *RUN !BOOT file, remember to include a CLI instruction before any OSRDCH attempt, as interrupts will be disabled. When using A=0, Y=0 for OSARGS, the control block will be found in the second processor, despite what the Advanced User Guide suggests.

BUILD YOUR OWN GRAPHICS TABLET (Part 1)

by Ben Miller-Smith

The analogue port of the BBC micro (model B) provides an easy way of interfacing a simple graphics tablet to the machine, and this can then be used to draw and copy diagrams onto the screen, or input relevant coordinates into a program. This article describes how to build such a graphics system, the first part detailing the construction of the tablet itself.

A graphics tablet connected to the analogue port provides an ideal way of entering a variety of visual images into the micro for display on the screen, and storage on cassette or disc. Drawings can be entered freehand, or existing diagrams traced out as required. Several such graphics tablets are commercially available, but at a price (see review in BEEBUG Vol.2 No.8), whereas the number of components required is minimal and the home construction cost is very small.

MATERIALS REQUIRED

(a) A Chipboard or Contiboard base, approximately 24" x 18", with a smooth (e.g. Melamine) finish. Available in 8mm or 12mm thicknesses (either suitable) from any DIY store at approximately £1.50 for a 24" x 36" panel, which you will need to cut in half to obtain the correct size.

(b) One metre of 5mm x 20mm (approx.) wood strip, to make the arms. If such strips are not available from your DIY store as straight timber, look for hardwood mouldings that are generally available in a variety of cross-sections, including rectangular. Approximate cost is about 50p.

COMPONENTS REQUIRED

(a) Two 10k linear panel-mounting potentiometers with at least 1" shafts. Available from Tandy shops (Part No. 271-1715 at 79p each), or Maplin Supplies (Part No. FW02C 'Pot Lin 10k' at 43p each).

(b) Three metres of four (or more) core cable, reasonably flexible. Available from most shops selling telephones, or from Maplin as Part No. XR66W '4-wire Phone Cable' in any reasonable length at 21p per metre. You

can use twin flex, or even single wire, if necessary, but it won't be so neat.

(c) One 15-way D plug (i.e. with pins) to fit the BBC analogue port, preferably with a covering shell and cable strain-relief fitting. Available from Maplin as Part No. BK58N 'D-Range 15 way Plug' at £1.45 (optional cover BK60Q 'D-Range 15 Way Cover' at £1.20), or many computer shops.

(d) Four rubber feet for the base-board. Available from Maplin as Part No. FW19V 'Feet Cab', at 8p for 4.

You will also need to have available a soldering iron and solder, drills in a range of sizes, some hand tools for wire cutting, and some adhesive.

Maplin components are available from their shops in Westcliffe, Hammersmith, Birmingham, Manchester and Southampton, or mail-order from their main office at Rayleigh in Essex (Tel. 0702-552911).

TABLET CONSTRUCTION

The plan and cross-section of the tablet are shown in diagrams 1 and 2. Drill a hole in the top left hand corner of the base board, about 1 inch in from the edges, with a diameter such that the threaded mounting collar of the first potentiometer is a tight (screw-in) fit. Screw the potentiometer into the base board from the bottom, with some glue if necessary to ensure that the whole potentiometer will not rotate when the shaft is turned. The shaft of the potentiometer will protrude through the board, ready to accept the first arm.

Cut a 13 inch length of the arm material and 0.5 inches from one end drill a hole to accept the board

potentiometer's shaft as a tight fit. Aim for the shaft/arm joint to be stiff enough so that in normal use the arm will always turn the shaft without slipping, but under abnormal stress (like dropping the tablet!) the joint will slip - however, if the joint is, or becomes, too slack a suitable adhesive can be used at the joint during final assembly. At the other end of the arm, glue the base of the second ('hinge') potentiometer to the top surface, such that the distance between the two shafts is 12 inches approximately. If the second potentiometer has not got a flat base (probably because the back end of the shaft protrudes slightly), drill a clearance hole in the arm so that the potentiometer can sit flat. The four rubber feet, referred to in the list of components, or just suitable blocks of wood, can be fitted to the underside of the four corners to provide a firm and level base.

The second arm is prepared with a similar tight-fitting shaft hole \varnothing .5 inches from one end, and a wood screw (or bolt) as a pointer at the other. Drill the hole for the pointer so that the effective length of the two arms is the same (i.e. arm 1 shaft centre to shaft effective length equals arm 2 shaft centre to pointer).

If it's not quite right, don't worry - corrections can be made in the software. Aim for the height of the pointer to be such that the second arm will be supported horizontally by its mounting on the hinge potentiometer shaft at one end, and the pointer resting on the base board at the other. Do not have the pointer tip too sharp or you may tear things being copied.

Complete the mechanical assembly. Press the first arm down the board potentiometer's shaft until it is flat on the base board, but can turn freely. Ensure that the potentiometer will not meet its 'end-stops' during normal use (rotate the shaft with respect to the arm if required). Glue the arm/shaft joint if necessary. Similarly, mount the second arm on the hinge potentiometer's shaft, ensuring a tight fit (glue if required), and free movement of the shaft between end stops. The pointer on the end of the arm linkage should now be able to reach almost all points on the base board, and all the action should be smooth with no jerkiness, sloppiness or slipping between the arms and the potentiometer shafts. This is most important and should be tested before final gluing.

ELECTRICAL CONNECTIONS

Four wires connect the Graphics Tablet to the computer Analogue port. VREF (pin 14) and ANALOGUE GROUND (pin 8) are connected to the two potentiometers in parallel, on the outer potentiometer tags. The wiper (centre) connection of the first (base-board) potentiometer is connected to CHANNEL 1 (pin 15), and the second (hinge) potentiometer wiper to CHANNEL 2 (pin 7).

In practice, carefully solder three wires to the hinge potentiometer (using multicore solder), twist them together, and run them back along arm 1 (attaching them with blobs of glue if necessary) and over the edge of the board (or down through an extra hole) to reach the first potentiometer, making the same two connections to the outer tags of this potentiometer, and connecting a fourth wire to its wiper. At the other end of at least 3 feet of cable solder the wires to the Analogue

port plug according to the table below, preferably using a soldering iron with a fine tip, and some sleeving over the joints to prevent accidental short-circuits.

D-Plug	Connection	Signal Name
Pin 7	Hinge potentiometer wiper (centre tag)	Channel 2
Pin 8	Both potentiometers 'bottom' tag	Analogue Ground
Pin 14	Both potentiometers 'top' tag	Vref
Pin 15	Board potentiometer wiper (centre tag)	Channel 1

Test the connections as follows. Clockwise rotation of either arm should give an increasing analogue voltage input to the computer. Run the

following little program and observe the displayed voltages as the arms are moved (ignore any jitter in the least significant digits).

```
10 MODE 7
20 REPEAT
30 PRINT TAB(0,5);SPC(40)
40 PRINT TAB(0,5);ADVAL(1)
50 PRINT TAB(20,5);ADVAL(2)
60 TIME=0:REPEAT UNTIL TIME>50
70 UNTIL FALSE
```

If either potentiometer is working in reverse, interchange the connections on its 'top' and 'bottom' tags (i.e. the two outer tags). If both are reversed it is probably easier to interchange the connections on pins 8 and 14 of the Analogue input plug.

This completes the detailed construction of the graphics tablet. Next month we will conclude this project by looking at how to calibrate the graphics tablet and at a program which provides a set of basic drawing routines to use with your new add-on.

HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINT

FASTER BASIC - P.J. Vincent

When performing certain operations in Basic, some programming techniques are more efficient than others (timewise). Generally speaking, REPEAT-UNTIL is faster than IF-THEN-GOTO, but FOR-NEXT is faster than REPEAT-UNTIL. A GOSUB is slightly faster than a procedure, contrary to what the User Guide suggests, and it is quicker to use global variables instead of local variables, again different to what the User Guide says. Turning off the ADC conversions though has very little effect upon timings.

CASSETTE USAGE OF WORDWISE - F. Duerden

If tape users of Wordwise want to produce several similar letters with just the top section different, then this can be achieved by means of the GF"name" command. If this is included in the DH section, and a number of files, all with the same name but different contents are present on tape, then Wordwise will produce a number of copies of the current piece of text, except that the headers will be different.

HOBBIT AND GDUMP - Tim Pearkes

Users of the Hobbit system may be interested to know that GDUMP will not function correctly with the Hobbit enabled. Disable it, and GDUMP then functions correctly. Several ROMs are apparently affected by the Hobbit system in this way.

TORCH CORRUPTION - John Satchell & John Sowden

When chaining between BBC Basic programs, or hitting Escape while running such a program, the Torch 280 (version v71) corrupts location &80.

DOCTOR SOFT MODS - Bjoern Floetten

There is an extra hidden command in Doctor Soft's 747 Flight Simulator; pressing 'T' will move the plane forward by 1 nautical mile.

ADVENTURE GAMES

Dungeon Master 'Mitch' invites you to join him in his adventure world

Welcome to the Dungeon mortal. Let me clear a space on this coffin lid for you to sit down. Ignore the dragon - he has already eaten so you are safe for a while. Well have you finally tired of zapping the Invaders? Perhaps now's the time to accept you're never going to get to the fourth screen on Killer Gorilla or see the sixth screen of Swoop. Never mind, there are other worlds to conquer where your brain can compete on equal terms with those nimble-fingered twelve year olds who can clear a Snapper screen while eating a hamburger with their other hand.

For those gentle readers who have never entered the world of Adventures let me briefly explain the delights. Before the coming of graphic screens and sound generators, programmers on mainframe computers were restricted to playing Noughts and Crosses and Hangman. Luckily, some bright spark realised that the text handling power of the computer, coupled with the imagination of a fantasy author, could produce a brilliant new dimension to adventure stories. Unlike a book, where the reader is unable to help or hinder the progress of the hero, the computerised adventure story allows the reader to decide the next move (e.g. shall he enter that dark doorway or not?). A wrong decision could result in an early and bloody demise. Well written adventures are an exciting escape into a world of magic and fantasy which fascinate both young and old. Too many adventure writers forget that the text must be skilfully used to draw the player into his world to amuse, intrigue and stimulate the imagination - boring text always means a boring game.

Bearing in mind that well written text is the first essential of an adventure, the use of sound and graphics is creeping in. The BBC micro

is restricted in its memory size compared with others and so far the introduction of graphics has normally been at the expense of the descriptive text. However text compression techniques are making it possible to include quite large graphic sections in some of the new games. Potential authors among you should remember that graphics should be treated with caution however, as pretty pictures are no substitute for exciting prose. Teletext graphics are becoming more popular as their use does not require the use of a graphics mode with its subsequent loss of memory. The latest game from Epic Software, 'Wheel of Fortune', has managed to combine a full sized game with a half screen teletext picture at every location without losing much in its text. However Bug Byte's 'Twin Kingdom Valley' seems to have placed its eggs firmly in its graphics mode basket with full screen graphics combined with limited lack-lustre text which does little for the imagination. Other games such as 'Vampire Castle' from Micrograf use small novelty teletext effects to introduce some spice into a mainly text game. I note that Level 9 computing intend to introduce graphics into their future games. [The grapevine says that these will start to appear soon. - Ed.]

So far Acornsoft have resisted the move towards graphics. Their traditional text-only games such as 'Castle of Riddles' and 'Philosophers Quest' have instead relied on amusing descriptions to create the scene. While this is perfectly acceptable (and preferred by some - do you need picture story books?), it's a pity they didn't use lower case lettering which is easier on the eye. This apart they can still hold their own against some of the glossy competition which uses coloured text for everything making it

impossible to read on some monitors and black and white televisions. Remember - rubbish written in pretty colours is still rubbish.

The Grand Wizard of Acornsoft has just sent me his latest offering called 'Gateway to Karos'. This adventure is another in the same Acornsoft mould - no graphics or sound. The format has, however, been changed slightly to include lower case letters and some coloured text. The location of the game is the mythical land of Karos where your task is to find the Talisman of Khoronz plus any other jewelled bauble you happen to stumble upon and then return safely through the magical gateway. As with earlier games Karos is populated with demons and magic users, oil lamps, screwdrivers and ruby brooches. There are 250 locations to explore and 65 objects to manipulate which should keep most glory hunters busy for quite some time. The inhabitants may be questioned by you to obtain clues and your questions, plus other commands, may be complex statements instead of the usual two word instructions such as 'FILL BOTTLE' (yes the bottle is back again!). In addition to falling rocks, and man eating wolves your condition gradually deteriorates unless you eat and drink occasionally. As usual that damned lamp starts to flicker just as you need it most so don't forget to turn it off when you don't need it.

I have enjoyed all Acornsoft's adventures and this is no exception as it sticks closely to their winning formula of lots of relatively easy problems which you know you will solve if you persist. Some other companies' adventures are too devious for their own good, and they have failed in the art of setting the problems at the level designed to satisfy master and novice alike. Karos is like a tin of Heinz beans; it is a safe buy, and you know before you hand over your money what you are getting, which although may not be a brave new leap forward, will not leave you feeling cheated as with some over-hyped games. I'm not sure that the trend towards complex command analysers in adventures is worth the trouble for Karos, like others, misinterprets some long

commands. I found I quickly returned to two word commands as it is usually quicker and safer. In addition I found that posing clever questions to the games inhabitants was a waste of time, as simply typing "ASK" seems to get the same reply - which incidentally is usually a baffling cryptic quote. The game certainly has hours of fun packed into it and so far I've found no mazes - thank goodness! I'd like to strangle the programmer who first introduced these as a feature.

Included with the game is an envelope containing answers to the various problems. This seems a better solution to the earlier idea of the postcard in Philosophers Quest which could be used to request clues from Acornsoft. I bet they didn't know what they had let themselves in for with that. So far I have resisted the temptation to open the envelope, but I hope they have laid it out better than Level 9 have done with their clue sheet. It appears to be impossible there to find only the answer to your problem without seeing the answers to everything else. As a final word on Acornsoft, whatever happened to 'Kingdom of Hamil' which they released last year? I've seen precious little of it in the computer press and I note that its name is excluded from the 'Also Available' list of titles on Karos' rear cover. Perhaps it has disappeared up one of its own twisty mazes or got stuck in the mud below the wishing well. [We actually have a copy of this game, but don't have the time to solve it! - Ed.]

For those heroes and heroines who have already crawled into some dark opening inside their micro and are currently beating their brains out against some unsurmountable puzzle, why not scribe the details on a piece of old parchment, mark it ADVENTURE DUNGEON, keeping it apart from any other queries you have and drop it into the dark opening of a pillar box to me here, at BEEBUG. I'll welcome any problems, hints or suggestions, so if you have any spare spells let me know.

P.S. Write in ink not blood, it scares the postman and agitates the dragon!

DOMESTIC ACCOUNTS EXTENDED

by David Fell

In the BEEBUG Vol.2 No.10 (April 1984) issue, we published a program called Home Accounts - Annual Budgets (or DOMAC for short), and this attracted quite a lot of feedback from members. One question that was frequently raised was that of dumping the screen to a printer. This update to the DOMAC program provides a couple of extensions to this program, including a quick universal screen dump.

Adding the new sections to the program is a fairly easy task. Load in your original version (which should not have been renumbered), and type in the new lines from the section that you require; for example, if all you want is the screen dump, type in only the lines from the screen dump section. Note that some of the lines in the original will be overwritten - this is intentional.

SCREEN DUMP

This is the main update to the original program, and consists of a few minor alterations to the main program, plus a section of code at the end of the program that pokes the screen dump to memory. There is an error detection check built into this, which will stop the program before any damage is done if you have made an error when typing in the DATA statements. The screen dump can be called at any time from within the program by holding down the Shift key and pressing Escape. The program will make a short tone, dump out the current screen to the printer, and then return to the main menu.

TUBE * COMMANDS

The original DOMAC program was 6502 Tube compatible with the possible exception of the * commands section, which tended to overwrite the program with the * command. Either set PAGE to &D00 or greater if running in the Tube, or make the short alterations listed below. Basic I users should not add the last two lines of the * command section. An asterisk (*) typed in at the menu now also calls the OS command section.

ACCURACY

Due to the way in which the program stored its numbers, there were occasional rounding errors. Whilst the degree of error here is probably less

than that in estimating the figures entered, it is still irritating. The correction is quite simple; change the factor of 100 to a factor of 1000 in the following lines where 100 is used for division or multiplication: 1750, 1890, 1950, 2080, 3040, 3090, 3120, 3150, 3910, 3990. Those of you with Toolkit may like to use the search and replace option to do this.

AND FINALLY...

Thankyou to all the members who have written in with comments and suggestions on this program, and also to TPL for providing assistance to members who wanted screen dumps before I wrote the little routine here.

Note - This month's magazine cassette / disc contains the complete updated DOMAC program.

NEW EDITION OF BIRNBAUM'S BOOK

Reviewed by Mike Williams

Assembly Language Programming for the BBC Microcomputer (2nd edition) by Ian Birnbaum, Macmillan, price £8.95.

Back in 1982 when the Beeb was still a mysterious adventure for most (that's if you were lucky enough to be able to get hold of one) there appeared a book that immediately became a best seller in its field. That book on assembly language programming has now progressed to a new second addition. So what has changed since we reviewed this book in BEEBUG Vol.1 No.9?

Certain changes stand out straight away, the cover is brown, not green, the whole book (apart from the program listings) has been typeset and (hurrah, hurrah) the book now has a full index. It is also marginally longer (by 12 pages) yet looks slimmer because of the thinner paper used. The price remains unchanged from the original.

The effect of typesetting has been to lose the somewhat distinctive appearance of the first edition and this also seems to have resulted in a more frequent occurrence of diagrams that are separated from the text that refers to them. On the other hand the program listings are now much clearer, and advantage has been taken of the LISTO command to produce better structured and more readable listings.

Essentially the content of the book is as before, with a progressive introduction to assembly language programming based on equivalent Basic concepts, and backed up by plenty of short example programs. I personally remain unconvinced of the use of Basic as an introduction to assembler as it propogates a high level language view of low level programming, but it is clearly an approach which has proved popular and succesful.

The chapters on indexed and indirect addressing are indeed models of excellence, and the text has been revised to take full advantage of the EQU and EQU commands of Basic II. The chapter on subroutines and interrupts has been extensively re-written to cover the extra features of O.S.1.2 such as events, and extra example programs have been included to illustrate the new material.

Solutions to all the exercises set in the book are provided as before and all the programs are now available on a single cassette, not two, for £9.00.

Without doubt this book must remain one of the best introductions to assembly language programming for the BBC micro that has been published.

TWO BASIC COMPILERS

Reviewed by Eric Glover

Although Basic is easy to learn and convenient to use, machine code is often preferred for its speed and compactness (think of all those machine code games). In consequence, a compiler which could convert Basic to machine code would seem to be high on everyone's priority list. Eric Glover looks at two compilers for Basic that have recently been released. Could one of these be the solution to your programming problems?

INTRODUCTION

When a program in BBC Basic is run, the Basic interpreter, built into the micro, interprets each instruction and carries out its function. Much time is spent on interpretation. For example, every instruction in a loop has to be interpreted each time it is encountered. Basic cannot 'remember' its meaning from the previous time.

As a result, interpreted Basic is slow compared to machine code, but programs written in Basic can be made to run much faster. If a Basic program is translated (or compiled) into machine code prior to execution, then the resulting program will run nearly as fast as one written directly in machine code, but with all the convenience of programming in Basic.

Once converted to machine code, the program can be saved in this format for execution at any future time using the command *RUN. The machine code version will probably also take up less memory space than the original Basic program. In addition, programs in machine code are very difficult to read, and this format provides a degree of program protection not possible with Basic.

SOME TERMS EXPLAINED

When using a compiler, the original Basic program is called the 'source' program, and the compiled machine code is known as 'object' code. With both the compilers reviewed here, the source code is prepared by typing it as usual into memory from the keyboard. Although convenient, this limits the size of the Basic program that can be compiled (or the size, and hence capability, of the compiler) as both must share memory together. Not only that, but memory space must also be found for the object code as well. This is not essential - most professional compilers take the source code from disc, and in turn send the object code back out to disc, thus allowing the compiler to occupy most of the available memory, and the Basic program to be very much larger.

THE LIMITATIONS

Ideally you should be able to compile any Basic program, but in reality it is impossible to fit a full compiler into memory, together with

both source and object code. Consequently compilers tend to accept only a subset of BBC Basic. Amongst the features often excluded are string variables, arrays, and real numbers. The two compilers reviewed here are no exception to this trend.

SALAMANDER SOFTWARE - TURBO COMPILER

This compiler is well packaged with a good clear manual. A tape version and a disc version of the compiler are included on the cassette as well as a demonstration graphics program. The manual provides full instructions for the use of the compiler and its transfer to disc if required. It is written in compact machine code (only 2K!) and sits below PAGE. The default addresses for the start of the source program and object program are &1500 (&2100 disc) and &2200 (&2800 disc) respectively, but they may be easily changed. Compilation is achieved by the *TURBO command, but there is no assembler listing. If an error is detected, the faulty line will be indicated (in hexadecimal!). If compilation is successful, the object program may be CALLED at the appropriate address, and also saved using *SAVE.

The facilities offered by the Turbo compiler are barely adequate to justify the term "compiler", and in many respects Turbo is little more than a high level assembler. The major constraints on the Basic source code include:

1. Except for line numbers and memory addresses, only positive hexadecimal single byte integers are allowed in the range 0 to 255, negative numbers being handled as complements.
2. Only the integer variables A% - Z% may be used.
3. Each Basic line may only contain one statement.
4. String variables are not allowed, but the string indirection operator '\$' is implemented in the usual Acorn fashion (as is '?' but not '!').

The following Basic keywords are implemented as normal or with only

minor restrictions: CALL (returns 6502 register values in A%, X%, Y%), CLG, CLS, AND, EOR, OR, END, GET, GOSUB, IF, INKEY, LET, MID\$, MODE, REM, RETURN, SOUND and VDU.

Basic keywords implemented with quite major restrictions are: CHR\$ (may only be used in PRINT statements), FOR-NEXT (must not be nested), PRINT (only strings may be PRINTED), and THEN (only a line number may follow).

The effect of several other Basic statements (ADVAL, ASC, BGET#, BPUT#, CLOSE#, DRAW, ENVELOPE, INPUT, LEN, MOVE, OPENIN, OPENOUT, PLOT, POINT, RND, and TIME) may be obtained by the use of the VDU statement, the indirection operator '?', or OSBYTE/OSWORD calls. Division is carried out by repeated subtraction.

As you may realise, a full list of Basic statements not supported by the Turbo Compiler would be rather long. These drawbacks may be less serious if it is regarded as a tool for compiling machine code subroutines, which may then be CALLED from interpreted Basic. Providing the user has a knowledge of O.S. routines (as given in the BBC User Guide) and a degree of perseverance it could prove useful in this respect. But writing a large program wholly for compilation by Turbo could well prove to be frustrating if not impossible with so many restrictions.

ACK DATA - BASIC COMPILER

Only the disc version of this compiler is reviewed here, but the tape version would seem to be identical in function. The compiler itself is written in Basic and occupies about 9K. Again you type in or load your source program as for a normal Basic program. The compilation is started by pressing function key f1. If all goes well, an assembler listing of the compiled code is produced, which may then be run by CALLING &1902 (&E02 for cassette systems). If, however, there is an error in the source program, then an error message usually appears indicating the offending line (if you are lucky). Occasionally, the compiler will go into an endless loop until Escape is pressed, whereupon it will confess that it can't compile the program.

The source program starts at &3900 and the compiler itself resides at &5300. These locations appear to be fixed. A source program of up to 6.5K (!) can be compiled with the following restrictions:

1. Arithmetic is two byte integer only (0 to 65535 or -32768 to 32767). Numbers may be in decimal or hexadecimal.
2. Only the variables A% - Z% may be used.
3. There are no string variables or string handling facilities.
4. Nested FOR-NEXT and REPEAT-UNTIL loops are not permitted.

The following BBC Basic keywords and operators are "supported": ADVAL, AND, CALL, CLEAR, CLG, CLS, COLOUR, DEF, DIV, DRAW, END, ENDPROC, ENVELOPE, EOR, FOR, GCOL, GET, GOSUB, GOTO, HIMEM, IF, INKEY, INPUT, LET, LOMEM, MOD, MODE, MOVE, NEXT, OR, PAGE, PLOT, POINT, POS, PRINT, PROC, REM, REPEAT, RETURN, RND, SOUND, SPC, SQR, STEP, TAB, THEN, TO, TOP, UNTIL, VDU, VPOS, '+', '-', '*', '/', '&', and '?'.

I say "supported" because although one is told that "the purpose and effect of these words is the same as described in the BBC User Guide", this is not quite true. For example, I could not call procedures recursively or use strings in INPUT statements. Neither of these restrictions was mentioned. Generally, however, the compiler worked well provided that spaces were avoided in the source program. Although more sophisticated Basic programs could be compiled with this compiler than with the previous one, its main use, I suggest, would be the same, the development of compiled machine code routines to be CALLED from within a Basic program.

CONCLUSIONS

Both compilers were robust, easy to use and did not overwrite the source program, although the ACK compiler annoyingly renumbered it 0, 1, 2...etc. Since the main attraction of using a compiler is the speed of the compiled code (the speed of compilation is irrelevant as it only has to be compiled once) it is important to say that both performed well in this respect. The ACK compiler was able to compile the first five PCW benchmarks which then executed roughly 15 times faster than with Acorn's Basic interpreter (itself very fast). Owing to its limited arithmetic facilities, Salamander's compiler could not compile these benchmarks except in a modified form, but the results were just as quick in general.

Overall, the ACK compiler is a more comprehensive offering than that of Salamander Software, and it produced more sophisticated machine code programs. For example, when printing a string it would set up a loop and access each character by indirect indexed addressing, whereas the Turbo compiler would simply load the accumulator with each character directly until it reached the end. The difference in capabilities of the two is reflected in their prices, but both exemplify the soft options of compiler design (rudimentary parser, no symbol table etc.) and are rather disappointing. However, given a little ingenuity and some expertise, both could be put to some good effect, e.g. shifting aliens. Despite their relative cheapness, it is difficult to give other than lukewarm approval to compilers that impose so many limitations upon the Basic programmer. As such, we look forward with anticipation to the future release of Computer Concepts' new Basic compiler.

POINTS ARISING

Z80 SECOND PROCESSOR REVIEW (BEEBUG Vol.3 No.4)

We have been asked to point out that M-Tec Basic, which was referred to in the comparison with the equivalent Torch ZEP100 system, is now bundled in with the Perfect software at no extra charge. The price of £126.50 only applies when M-Tec Basic is purchased as a separate software item.

IMPROVED FUNCTION KEY LABELS (16K)

by Graham Crow

In BEEBUG Vol.2 No.9 we published a program to print out function key labels on an Epson printer. Graham Crow has now improved this program to produce even neater function key labels on an Epson FX-80.

By using superscript mode for the text, it is possible to achieve a whole line of bold heading and still have 9 lines of text. Using reverse feed, the border is printed in single strike mode, while the text is in double strike. Several examples of excellent keystrips produced by the program have been selected to illustrate this article.

Type the program in and save it on cassette or disc. The program already contains data to produce a keystrip for ASTAAD2 published in BEEBUG Vol.2 No.9. If you run the program, then this will be the keystrip printed.

You can easily add further lines of data for other keystrips of your choice and simply change the value after the RESTORE in line 130 to point to the start of the data for the keystrip you want to print. This allows you to maintain one program that is capable of printing any one of several keystrips.

The program also has double broken lines above and below the function key

label. Cutting between these will ensure that the keystrips fit your Beeb exactly.

For each keystrip you will need 9 lines of data, the first to contain the keystrip title, and the remainder will each require 10 data items to be printed on that line, as shown in the example provided.

Before you print a keystrip with this program, you will need to make sure that the buffer on your printer is switched off because user defined characters on the printer use the same memory space as the buffer. This can be done by removing the cover for the DIP switches and making sure that switch 1-4 (switch number four in the row of eight switches) is in the off position. Then you can run the program and see the results for yourself. Remember though, to turn the buffer back on when you have finished.

BEGINNERS

THIS WAY

DEBUGGING PROGRAMS

(Part 1)

by Ben Miller-Smith

This month Ben Miller-Smith presents the first of two articles on coping with errors in programs. This can be a difficult task for the beginner, despite the excellent error reporting on the BBC micro. This month's article concentrates on some of the problems that may arise from errors introduced when typing in a program.

1. INTRODUCTION

The BBC computer and its Basic interpreter provide quite comprehensive and powerful error detection and reporting routines which are a big help in debugging programs, especially as a program of any complexity is very unlikely to work quite as expected first time. This may create a whole series of error messages or strange results which can be quite difficult to sort out. If you have copied programs out of magazines or books you will

probably have made some typing errors and found some difficulty in getting the program to run properly. Various different troubleshooting techniques may be necessary depending on the nature of the apparent errors, but before we look at them in detail it is well to understand the error handling facilities on the BBC micro, as these can affect debugging.

2. ERROR HANDLING ON THE BBC

In normal operation the BBC's Basic interpreter will report errors as a descriptive message, with an associated program line number if possible - perhaps the most familiar is the result of pressing the Escape key while a program is running, which usually results in a message of the form:

```
Escape at line 210
```

indicating that the program just happened to be executing line number 210 at the time the Escape key was pressed. Similarly, if line number 410, say, had been incorrectly entered as:

```
410 Y = SIN(X)
```

then the error message should be:

```
Missing ) at line 410
```

which is a pretty clear statement of the problem. However, complications in debugging a program may arise if the error handling mechanism of the BBC computer has been modified with an 'ON ERROR GOTO...' or similar statement, usually near the start of a program, or in an initialisation procedure. In this case the reporting of the action following any error is the responsibility of the programmer, and in some cases this leaves much to be desired [Hopefully not with the programs we publish in BEEBUG - Ed.]. Using the ON ERROR type of statement is one way of disabling the Escape key, since depression of the key creates, as far as the computer is concerned, error number 17 ('Escape'). The programmer might wish to cause the program to start again when the Escape key is pressed, so a statement of the form:

```
10 ON ERROR RUN
```

is likely to be included near the start of the program. This is all very well, but if you have copied a magazine program and unfortunately introduced some errors, then when the program comes across the first error it will restart, find the error again, restart, and so on for ever. The simplest thing to do, having pressed Break and typed OLD (carefully! Oh L D, not zero L D), is to disable the ON ERROR statement temporarily by putting a REM in front of it thus:

```
10 REM ON ERROR RUN
```

which will enable the normal error reporting system to operate - at least you now have a chance of finding and correcting any errors. When you think

the program is operating correctly you can always restore the ON ERROR statement to its original form if necessary. Always look for this type of problem if you have copied or modified someone else's program, and it either appears not to work at all, or seems to run for a time and then unexpectedly restarts.

The BBC computer keeps an internal record of the last error encountered, and the line number associated with it, if any. This information can be recalled at any time by examining the values of two pseudo-variables called ERR (the last-error number) and ERL (the line number). This facility is sometimes used in programs to give a 'tidy' error detection and reporting routine, especially where a program has put the computer into an unusual state (e.g. small text window, different colours, a large character mode, etc., etc.) The additional command 'REPORT' will cause the error message associated with a given ERR number to be printed, so a nice way to handle errors, including terminating a program with the Escape key (error number 17) is to include the statement:

```
9000 IF ERR<>17 THEN ON ERROR OFF:
MODE 7: REPORT: PRINT "at line"ERL: END
9010 REM Tidy up following Escape
9020 VDU 15: VDU 20: VDU 26: REM Res
tore defaults, etc.
9030 END
```

At or near the start of the program this error-handling routine would be switched on with a statement of the form:

```
10 ON ERROR GOTO 9000
```

Note that this method of error interception gives the programmer complete control over the system following any error and not just Escape, as in the example above. It is thus possible to trap all run time errors such as 'Division by Zero' or trying to extract 'Negative Square Roots', to do something about it, and then return to the main stream of the program at some suitable re-entry point - the availability of such restart points will markedly depend on how well the program is structured.

3. COMMON ERRORS

If the computer comes across an instruction that it cannot understand it will stop running the program and do its best to report the type of error encountered, and the line number currently being executed in the program. The commonest cause is a typing error, or your misunderstanding of the format required for a particular type of instruction. For example, a Basic line reading:

```
320 PRONT "Enter a new position"
```

will cause the error message:

```
Mistake at line 320
```

since PRONT is not a valid Basic word, and 'Mistake' is the computer's way of saying that it cannot make any sense of the given line.

Sometimes the error reporting system has a problem in identifying the exact cause of the error, as in the line:

```
400 newheight = time ** droprate
```

which will result in the message 'No such variable at line 400' because the second * is interpreted as a variable name rather than as an extra arithmetic symbol. The 'No such variable' error is probably the most common type of mistake, mainly due to typing errors in variable names, not taking care with upper and lower case letters, or missing out % signs at the end of (integer) variable names. A more subtle variation of this error may occur if early on in a program a variable name is mis-spelt, but is referred to correctly in other lines of the program. In this case when you list the line that has been reported as faulty you may find there is nothing obviously wrong with it. For example:

```
360...
370...
380 droprat = startrate + gravity *
time
390...
400 newheight = time * droprate
410...
```

will again result in 'No such variable at line 400' even though line 400

looks perfect. There is nothing for it but to look back through the program for previous occurrences of the variables named in the line reported as faulty and so find the real problem, which in this case is in line 380 (too easy!).

Probably the worst possible instance of this type of error, or at least the one that can be hardest to find, can occur when using a procedure in a program, especially one that has many arguments. When the procedure is called the necessary parameters (usually variable names) are listed in brackets after the procedure name, and their values are substituted into the corresponding arguments in the definition of the procedure. The problem is, if one of these variable parameters is invalid then an error will indeed be reported, but at the line number of the procedure definition, not the line number that

called the procedure (which has at least got the faulty variable name included in it). If the procedure reporting the error is called only once from elsewhere in the program then it is not too difficult to trace back to the problem area - but a commonly used procedure could be called quite often, and it may not be easy to identify which call is creating the fatal error.

Clearly, some detective work may be necessary to identify the exact cause of errors reported by the computer when you first run a new program (or modify an existing one), but at least the BBC computer has quite comprehensive error checking and reporting, even if it is sometimes misleading. The best approach is to take the initial debugging carefully, and be prepared to look not only at the line reported as faulty, but at possibly related lines. With the right attitude of mind, you may even enjoy the puzzle presented.

HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

ANOTHER USE FOR *BASIC - S.R. Linter

If you have both Disc Doctor and Watford DFS in your machine, then Disc Doctor traps any use of the *EDIT command before the DFS can react to it. By typing in *FX187,n where n is the number of the ROM socket holding the DFS (0-15), *BASIC will now perform the equivalent of *EDIT directed straight to the Watford DFS.

AMUSING *FX CALL - W.J. Hicks

Following on from the weird GOTO hint, try the following:

```
*FX243,129
*FX243,151
```

These will produce some rather strange effects on the screen. Make sure that you have saved whatever is in the machine before hand. Press the Break key or Return a few times to produce more effects, or experiment with other values! Control-Break will reset the machine afterwards.

POWER UP RESET

If you want to simulate a power up reset (which does not check the *FX247 flag), then keying *FX151,78,127 followed by pressing Break will suffice.

BASICALLY MISTAKEN - Roger Garratt

Basic gets confused in assembler with variable names that begin with a capital 'A'; it thinks you want Accumulator addressing, and assembles accordingly. There are two solutions: use lower case variable names, or enclose the variable in brackets.

LENGTH OF A FILE

If you want to find out quickly the length of a file, use the following code, where name\$ holds the file name:

```
len%=EXT# OPENIN name$:CLOSE#0
```

LONG DISC FILES - Dudley Long

To create a large disc file, use a command like:

```
*SAVE FILE 0+31E00
```

This saves a considerable amount of time over other methods.

CROSS REFERENCE LISTER (16k)

by Ian Gooding

This month's utility is a very useful program that provides a cross reference listing of a Basic program. It builds up lists of all the variables, procedures, functions, etc used in the program, and the lines at which they are referenced. This program is a must for the serious developer of Basic software.

INTRODUCTION

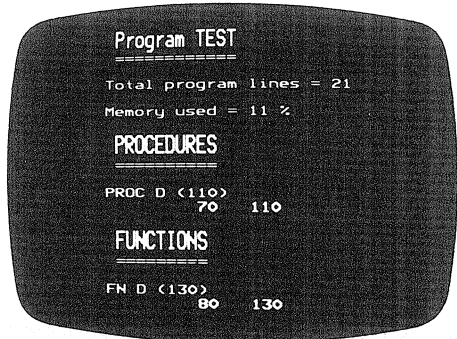

The purpose of this program is to provide the user with a list of names and lines numbers used within his Basic program to aid in debugging and documentation. The program searches for procedure and function names and the lines at which they are referenced; it deals similarly with variable names and lines which have GOTO or GOSUB statements referring to them. Support for printers is included within the program, and any or all of the search options mentioned above may be omitted. The total number of lines in the program is always displayed after the program has been run, as is an indication of the amount of remaining free memory.

USING THE CROSS REFERENCER

The cross referencer should be typed in and saved away for future use. The program to be analysed should be first saved onto disc or tape (provided that for tape you have motor control).

The program as listed appears longer than it really is as many REM statements have been included to assist those who wish to examine the workings of the program. All REM statements may be omitted when you type the program in. Readers with Basic I should replace OPENUP at line 1200 with OPENIN.

Once run, the cross referencer prompts for your choice of the available options. These include selecting output to the printer, and the checking for procedures, functions, variables, and GOTO and GOSUB references. There is an option to reference all the options without having to type in 'yes' to each of them. Having answered the questions mentioned above, the program prompts for the file name of the program to be analysed, and then proceeds to build up the cross reference list.

While the program is running, it displays on the screen the current line being scanned, the most recent procedure, function or variable name read, and the last line number referenced by a GOTO or GOSUB statement. No information is displayed for any option omitted (e.g. no reference to line numbers with GOTO or GOSUB) though the current line number is always displayed.

Once the analysis has been completed, the program lists out the information collected with coloured highlights, with the corresponding text sent to the printer if selected. For an example of the output produced, see the sample listing included with this article.

The program functions quite happily in a 6502 second processor (there is a significant speed improvement in fact). Once the run is finished, you may obtain the list of references again by typing PROCreport.

The necessary data is contained within the program in a fairly complex manner, and space does not permit here a detailed explanation of how this arranged. For the more adventurous

reader, an examination of the program should prove quite interesting as it is very well structured.

LIMITATIONS

A consequence of writing a utility like this in Basic, and keeping the program to a reasonable length is that some simplifications have to be made. Any computed GOTO or GOSUB line number references are ignored (these are impossible to determine in advance anyway). DATA, REM and assembler comment blocks are ignored, and any * calls are treated as variables; e.g. *FX243,129 is treated as a reference to the variable FX243. The program will mark arrays such as A(..) as A(, but for arrays such as A\$(..) or A\$(., then only A% or A\$ will be displayed.

To provide even more help for programmers, we have included an additional program on this month's magazine cassette/disc. This is the program PACK, first published in BEEBUG Vol.1 No.9, which allows you to remove spaces, REMs and comments from long programs to save space. The program is accompanied by sufficient instructions for its use if you don't have the original magazine handy. These programs together with the performance analyser published last month provide a most useful set of utilities for serious Basic programmers and we expect to add further such utilities in future issues.

DELAY LOOP

A REPEAT UNTIL TIME ... delay loop doesn't have to use positive values, as can be demonstrated by:

```
TIME=-500
```

```
REPEAT UNTIL TIME>0
```

This also means that different delay times (maybe set in another program) can use the same delay loop instruction.

In a standard Beeb there are four paged ROM sockets for you to use. If you have Basic in one of them, as most people do, and then add a DFS chip, you are left with only two vacant sockets. With probably in excess of a 100 different ROMs now available for use with a Beeb, this is clearly not sufficient. Fortunately, the circuitry that handles paged ROMs can cope with up to 16 devices. In BEEBUG Vol.2 No.6 we reviewed ROM expansion boards from Watford Electronics, Sir Computers and ATPL. All the boards in that review are still available although the Watford board has undergone a significant improvement, and now includes full on-board buffering. In this review we will be looking at some of the more recent boards to see how they compare.

For reference, the basic information on each board, including those reviewed before, is shown in the table above.

EXPROM ROM EXPANSION BOARD

The overall construction of this board is to a high standard. All the ROM sockets are numbered and easy to identify, as are all the other components such as the links and switches. RAM may be used in 2K or 8K chips; with the 2K devices there can be a maximum of 8K, whilst the 8K devices provide a maximum of 16K. There is a plug-in link for each socket to enable a 'wait state' for EPROMs slower than the normal 250ns.

On the standard board two toggle switches are mounted along the rear edge of the board, and these allow

sockets 14 and 15 to be switched out, or disabled. Two further switches to disable sockets 12 and 13 can be fitted as an option at the time of purchase, bringing the price of the board up to £65.50. When the board is positioned inside the computer, access to the toggle switches is via the slot at the rear of the case. The facility to switch off a ROM can be used to overcome the problem of one ROM interfering with the operation of another. [See also the review of Watford's ROM Manager elsewhere in this issue - Ed.]

A 'zero insertion force' socket can be provided as an alternative in position 4 on the board. This allows ROMs to be inserted and removed easily without much risk of damage. The Exprom board may be installed inside or outside the computer and this position may be changed as and when required.

Connection to the computer requires removal of the 6502 CPU and all the paged ROMs in the BBC micro. These are then plugged into the appropriate sockets on the Exprom board. A 40 way ribbon cable from the Exprom board is then connected to the 6502 socket in the micro with a DIL header plug.

When finally clipped into place on its pillars, the board is very secure and stable. The position of various chips on the board makes the insertion and removal of ROMs more difficult than it might be. However, if you use a proper ROM removal tool (highly recommended and cheap) then you will have no problems, particularly as the sockets are of the older type and it requires only a small amount of force for insertion and removal.

The documentation supplied with the board was in the form of an excellent manual of some 20 pages. The section on the link options takes a fair amount of close reading to understand fully but should not cause any real problem.

RAMAMP ROM EXPANSION BOARD

This board supports seven paged ROMs along with three on the BBC board (the fourth is taken up by the new board). It will accommodate 8K or 16K EPROMs,

and by altering some links three of the sockets can utilise 24 pin 4K devices.

Although the quality of construction is very good, the design is less impressive. A four-way ribbon cable must be soldered to four of the pins of IC76 on the main BBC computer board. On some versions of the BBC micro, this IC is soldered in place. Personally, I do not like the idea of soldering direct to the pins of an IC like this. It is difficult to attach four wires to the closely-spaced pins without shorting them out, and there is the possibility of damaging the IC if too much heat is applied trying to rectify mistakes.

The documentation supplied with this board consisted of two sheets of clear instructions and a single sheet of diagrams. If you live close enough to their workshops (see address at head of review), then Ramamp will fit the board for you at no extra cost.

RAMAMP ROM/RAM EXPANSION BOARD

This board is very similar to the Ramamp ROM board described above, except that it can accommodate paged RAM. It allows the use of 8k and 16K EPROMs but not the 4K type. There are two versions of the board available; one fitted with 16K of paged RAM (costing £47.00) and the other with two 16K pages of RAM (costing £59.00). The documentation consisted of just a sheet of text and a sheet of diagrams.

ARIES B-12 ROM/RAM EXPANSION BOARD

This system comprises three boards. The main board carries the ROMs and a second the buffering and decoding chips. The quality and standard of construction of these three boards is very impressive indeed.

If you have the Aries B-20 RAM expansion board fitted (reviewed in BEEBUG Vol.2 No.9), the 6502 CPU is not removed and a 5-way ribbon cable is plugged into the socket provided on the B-20. If not, the 6502 is plugged into the other small board provided with the B-12 ROM board. This small carrier board is then plugged into the 6502 socket on the BBC by means of pins on the underside and the 5-way ribbon cable plugged into the socket provided on this.

The main board supports up to twelve paged EPROMs and 16K of paged RAM may be added in two 8K devices. All the sockets are numbered very clearly for ease of identification and are arranged in a 2 x 7 layout. There is no battery backup facility provided for the paged RAM.

Documentation consisted of a very comprehensive sixteen page manual, with clear instructions and plenty of illustrations.

COMPUTER VILLAGE CVX16 ROM/RAM EXPANSION BOARD

Again the quality and construction of the double sided PCB is excellent and features some eighteen buffering and decoding chips.

The board will accept 8K and 16K EPROMs and has a paged RAM facility allowing the use of 2K CMOS or NMOS RAM devices up to a maximum of 16K. A battery backup facility is provided for the paged RAM as standard, requiring only the addition of the Ni-Cad battery. Paged RAM on this board can be write-protected under software control. Using the cheaper 2K RAM chips uses up 8 sockets allowing space for only 8 ROMs to be fitted at the same time.

CONCLUSIONS

I am pleased to say that all the boards worked without fault during testing. Every board was operated continuously inside the computer for a period of at least six hours and none suffered with overheating. Because the Computer Village board is installed so close to the computer's RAM chips, which produce a good deal of heat, it was soak tested for twelve hours but continued to work perfectly.

Which of these boards you choose will depend on the cost, the facilities you need and the ease of fitting. If you change ROMs regularly, the convenience of doing this will be important to you.

The Ramamp ROM board provides an inexpensive solution for those needing up to six extra ROM sockets. The ROM/RAM version is particularly good value when you consider the RAM comes with the board and enables you to store some of your ROMs on disc and load them

in when needed. However, you must be prepared to undertake some soldering (as described above) when fitting either of these boards.

The Computer Village board needs modifications, I feel, to provide a more satisfactory way of attaching it to the computer, and to make it more secure. It is sad that little thought seems to have been given to this, yet the board itself is so well made and provides good facilities. This is the only ROM/RAM board in the review that can provide battery backup for the paged RAM. I hope Computer Village give some attention to the problems I have mentioned before they release any new version of this board.

The last two units, the Exprom and Aries boards, both provide the best way, in my opinion, of attaching a ROM board to your computer. That is externally in its own case. A great deal of thought went into the design of both of these boards and it shows.

If it's facilities you're after then the Exprom board may be considered as the unit for you. I have yet to come across another ROM/RAM board that has as many operating options as this one. My only dislikes about this board were the unco-operative ribbon cable and the slight difficulty in removing ROMs. Don't let this put you off too much though, this unit is well worth serious consideration even if you don't need all the extra facilities.

Finally, my own personal choice out of all these boards is the Aries B-12. It is beautifully made, easy to fit, provides all the facilities that I need and is realistically priced. It can be mounted internally and externally, removal of ROMs is straightforward and the unit is secure and stable. True it supports only twelve paged ROMs but the paged RAM can be used to load some of your ROMs from disc. I find it hard to fault this board in any way.

Of the boards reviewed previously that produced by ATPL still stands out as being excellent value, especially at the BEEBUG members price. Our previous comments on the other two boards by and large remain valid. Ed.

BEEBUG

Workshop

FORMATTING TEXT

by Surac

This month we take a look at the problem of printing text on the screen without splitting words over the end of a line. A method to achieve this is explained in this month's workshop together with a description of a machine code routine to put this into effect.

Imagine, say, that you are writing an adventure game and that you want to print out the description for the current room. You are working in mode 7 (with a screen width of 40 characters), but the text you have is over 40 characters long, and you wish to avoid any breaks in the words. Obviously, you could type in the text with breaks at the appropriate points, but this would be tedious, and make changing a description inconvenient. What you need is a routine that takes each word, and looks to see if it will fit into the current line totally, or if you need to start on the next line before you can print it. What we're going to do is discuss exactly how we want our formatting routine to work, and then I'll provide an example of how to code it written in machine code for you to use.

Basically, the way to print the text in the required format is to take each word, add its length to the current position of the cursor on the screen, and compare this with the width of the screen that we are using. If the new position is before the end of the line, we print the next word and a space, and carry on. If the new word finishes exactly on the end of the line, we just print the word, but no space. If the word overlaps, we start on the next line down, and print the word and a space. This process will ensure that each line is filled with whole words (but not right justified).

The routine listed here includes a short program in Basic to demonstrate its use. Type it all in and save it to tape or disc first (particularly

important with machine code which may completely corrupt the program when run if any typing errors have been introduced). If the program is then run, it will assemble the machine code, and then prompt for the mode you wish to test it in. You will also be asked for a string to format, and the screen width you wish to use. If you want to use the full screen width for the mode selected, just enter zero. The demonstration is repeated as often as you wish.

Using the routine in your own programs is quite simple. All you have to do is to add the machine code routine contained in the procedure PROCassemble, the two functions FNegub and FNegus (the use of these is equivalent to the functions EQUb and EQUs available in Basic II and Hi-Basic), and the procedure PROCformat. The procedure PROCassemble should be called to assemble the machine code before PROCformat is used in your program. The format procedure takes two parameters, the string to format, and the line width to be used. The width is supplied as a parameter in case you should want to use text with a width less than that of the full screen (perhaps with a text window for example). However, if the width is specified just as zero then the current mode is used to determine the screen width using a small look-up table (the data at line 2150). This is much easier in machine code than using an expression to calculate the result as in last month's Basic program.

The formatting routine could quite easily be used by itself in a machine

code program. In this case the X and Y registers on entry point to a block of text, with a zero byte marking the end. The block can be virtually any length, but an individual word should not be longer than 255 characters. Note that Return and other characters that don't occupy a single space on the screen will lead to errors in the accuracy of the formatting.

WATFORD ELECTRONIC'S ROM MANAGER

Reviewed by David Fell

Product : ROM Manager
 Supplier: Watford Electronics,
 35 Cardiff Road
 Watford
 Price: £21.50 (special price to
 BEEBUG members)

One of the problems that may arise now that so much ROM based software is available for the Beeb is that, almost inevitably, a well populated machine will contain two or more ROMs which have been programmed to recognise the same command; perhaps the most common example being the use of 'EDIT'. BEEBUG has already proposed a 'ROM Rule' to alleviate this situation (see last month's editorial), and now Watford Electronics have come up with 'ROM Manager' which is intended to provide comprehensive management of all your installed ROMs, including conflicts with ROM commands.

Probably the most useful feature is the *DIRECT command. This allows any command to be passed directly to a specified ROM. Because this command is so valuable, says the manual, there is an alternative command name for performing the same action; viz the *VECTOR command. *STOP and *START are two commands that allow sideways ROMs to be turned on or off. All * commands are then ignored by any ROMs in an 'off' state.

There are also various other commands provided by ROM Manager. These will list out the ROMs present in

the machine, display detailed information on a specified ROM, list the contents of a ROM, edit memory, and calculate the checksum of a given ROM. There is also a command to list the function key definitions (although this doesn't cope with a delete character in a definition), and a command to display help on the first 22 (0 to 21) FX calls. This seems to be rather a space filler as the Advanced User Guide contains most of the relevant facts.

The final selection of commands allows you to develop sideways ROMs in normal memory (not sideways RAM), and to have all service calls directed to your 'ROM'. This is a nice feature, even if of interest to just a few.

If your Beeb is filled with ROMs, as mine is, then Watford Electronics' ROM Manager will at last allow you to avoid many of the conflicts and other problems that have bedevilled the use of ROM-based software until now. It is worth it for this feature alone.

BEEBUG has negotiated a deal with Watford Electronics whereby members may purchase ROM Manager for just £21.50 (including VAT and postage). Send your order direct to Watford Electronics. It is ESSENTIAL to quote your BEEBUG membership number, and state that you require the BEEBUG discount.

HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

6502 TUBE AND THE GRAPHICS ROM - Roy A. Harcup

To use the facility of the Computer Concepts' Graphics ROM to pass integer parameters over the Tube, you need to form a string and place this in an OSCLI statement. For example,

```
*IN 1 500 Y%
would be encoded as
A$="IN 1 500 "+STR$Y%
OSCLI A$
```

Do not, however, try to use the trig routines built in to the Graphics ROM in this way, as these will not work, and the integrity of the machine cannot be guaranteed.

WEE SHUGGY (32k)

by Hugh Darby

If you enjoyed Block Blitz published in BEEBUG Vol.2 No.8 (acclaimed by many members as one of our best ever games) then you will certainly like Wee Shuggy, a game about a small guy trapped in a dungeon. He needs your help to find several keys and escape from the nightmare world in which he finds himself.

Wee Shuggy is a version of the popular computer game called 'Manic Miner' in which the player has to fetch all of the keys to open a grating so that he can escape from the dungeon. There are various obstacles on the way including thorn bushes, floors that collapse as you walk on them, stalactites and conveyor belts.

You lose a life if you jump into a stalactite or a thorn bush, and then have to start the current screen from the beginning again.

You have three lives in all, and there is a high score table and instructions in the program. The game uses just three keys to control the movements of the man, 'Z' and 'X' for left and right, and 'Return' for jump.

There are six different dungeons in this fast and colourful game, and each one provides a challenging, enjoyable and often frustrating experience.

We are sure that once you start playing Wee Shuggy you will agree that this is one of the most outstanding games that we have published in BEEBUG. The time and effort spent typing the program into your micro will be well rewarded.

PROGRAM NOTES

The program is well structured, but care is still required when typing it in. Extensive use is made of user-defined characters set up in the procedure PROCcharacter from line 3490 onwards. These characters are used extensively in displaying the different screens used in the game (procedures screen, screen2, screen3, screen4, screen5, and screen6) by putting the character codes in a series of VDU statements in each case. The VDU statement is more concise as only the

character code is required (224, 225 etc) rather than the character itself (CHR\$224, CHR\$225 etc) as would be needed in a PRINT statement. It is also easy to include any of the other VDU codes (in the range 0 - 31) to change colour, move the cursor etc as required.

For speed, the program also incorporates a short machine code routine PROCassem (to check on the screen character at the current cursor position) and uses direct memory access (the procedure PROCobject for example).

All the procedures have reasonably meaningful names and you should be able to identify their functions without too much difficulty.

NUMBER HUNT (16k)

by Kevin Allen

Hunt the Numbers is a simple but fast game written in Basic. It incorporates coloured graphics in mode 5 and at the fastest level is very quick and extremely challenging.

Your man is a number-eating beastly, or a kind of number-cruncher, I suppose, whose world consists of a nice bright yellow square. Within this, by the magic of computers, ever increasing numbers keep appearing as a temptation to your man to raise his calorific intake for the day. But as you move him to digest these numeric morsels, other nasty monsters will give chase all round the board with only the demise and consumption of your innocent glutton as their objective. These chaps are number-cruncher gulpers and they increase in quantity with your man's success. With higher levels of skill, selected at the beginning of the game, these aggressors become faster and more direct in their descent upon your ever-hungry number-cruncher which can result in a peculiarly loopy dance around the board's surface.

Controls to change the horizontal and vertical directions of movement are the usual 'Z', 'X', and '*' and '/' keys but it's important to note also that simultaneous use of a horizontal and a vertical control key will produce a diagonal motion, which is just as well because the 'nasty monsters' have no qualms about cutting corners when they're chasing you.

IF YOU WRITE TO US

BACK ISSUES (Members only)

All back issues are kept in print (from April 1982). Send 90p per issue PLUS an A5 SAE to the subscriptions address. This offer is for members only, so it is ESSENTIAL to quote your membership number with your order. Please note that the BEEBUG Reference Card and BEEBUG supplements are not supplied with back issues.

SUBSCRIPTIONS

Send all applications for membership, subscription renewals, and subscription queries to the subscriptions address.

MEMBERSHIP COSTS:

U.K.

£6.40 for 6 months (5 issues)
£11.90 for 1 year (10 issues)

Eire and Europe
Membership £18 for 1 year.

Middle East £21

Americas and Africa £23
Elsewhere £25

Payment in Sterling preferred.

<u>Subscriptions & Software Address</u>	<u>Subscriptions and Software Help Line</u>
BEEBUG PO BOX 109 High Wycombe Bucks	St.Albans (0727) 60263 Manned Mon-Fri 9pm-5pm

PROGRAMS AND ARTICLES

All programs and articles used are paid for at around £25 per page, but please give us warning of anything substantial that you intend to write. In the case of material longer than a page, we would prefer this to be submitted on cassette or disc in machine readable form using "Wordwise", "Minitext Editor" or other means. If you use cassette, please include a backup copy at 300 baud.

HINTS

There are prizes of £5 and £10 for the best hints each month.

Please send all editorial material to the editorial address below. If you require a reply it is essential to quote your membership number and enclose an SAE.

<u>Editorial Address</u>	BEEBUG PO Box 50 St Albans Herts

BEEBUG Publications Ltd (c) April 1984.

BEEBUG MAGAZINE is produced by BEEBUG Publications Ltd.

Editor: Mike Williams.

Assistant Editor: Geoff Bains, Production Editor: Phyllida Vanstone.

Technical Assistants: David Fell and Alan Webster.

Managing Editor: Lee Calcraft.

Thanks are due to Sheridan Williams, Adrian Calcraft, John Yale, and Tim Powys-Lybbe for assistance with this issue.

NEW BEEBUG BINDERS

We have produced a new hard-backed binder for the BEEBUG magazine. These binders are dark blue in colour with "BEEBUG" in gold lettering on the spine and allow for the whole of one volume of the magazine to be stored as a single reference book.

The new binders now have a slightly larger capacity to accommodate 10 thicker BEEBUG magazines, and are supplied with 12 wires. This enables the index and the latest copy of the supplement to be included within the binder if required. Individual issues may still be easily added and removed, allowing for the latest volume to be filed as it arrives.

The price of the new BEEBUG binder is £3.90 including VAT. Please add 50p post and packing for delivery within the UK. Overseas members please send the same amount, this will cover the extra postage but not VAT.

BEEBUGSOFT, PO BOX 109, High Wycombe, Bucks, HP10 8HQ.

BEEBUG NEW ROM OFFER

1.2 OPERATING SYSTEM

A special arrangement has been agreed between Acorn and BEEBUG whereby BEEBUG members may obtain the 1.2 operating system in ROM at the price of £5.85 including VAT and post and packing. The ROM will be supplied with fitting instructions to enable members to install it in their machine. If the computer does not subsequently operate correctly, members may take their machine to an Acorn dealer for the upgrade to be tested, which will be done at a charge of £6.00 plus VAT. This charge will be waived if the ROM is found to have been defective. If the computer has been damaged during the installation process, the dealer will make a repair charge.

ADDRESS FOR 1.2 OS:

ROM Offer, BEEBUG, PO Box 109, High Wycombe, Bucks, HP10 8HQ

THE BEEBUG MAGAZINE ON DISC AND CASSETTE

The programs featured each month in the BEEBUG magazine are now available to members on disc and cassette.

Each month we will produce a disc and cassette containing all of the programs included in that month's issue of BEEBUG. Both the disc and the cassette will display a full menu allowing the selection of individual programs and the disc will incorporate a special program allowing it to be read by both 40 and 80 track disc drives. Details of the programs included in this month's magazine cassette and disc are given below.

Magazine cassettes are priced at £3.00 and discs at £4.75.
SEE BELOW FOR FULL ORDERING INFORMATION.

This Month's Programs Include:

Superb action game Wee Shuggy, a useful and comprehensive Cross-Reference Lister for Basic programmers, BEEBUG Workshop Text formatting routine, Auto-Keyword Generator for Basic, full extended version of the Domestic Accounts Home Budgeting program, improved utility for printing function key labels, another challenging game Number Hunt, and as an extra a copy of the BEEBUG Pack program for squeezing unnecessary spaces and comments out of Basic programs.

MAGAZINE DISC/CASSETTE SUBSCRIPTION

Subscription to the magazine cassette and disc is also available to members and offers the added advantage of regularly receiving the programs at the same time as the magazine, but under separate cover.

Subscription is offered either for a period of 6 months (5 issues) or 1 year (10 issues) and may be backdated if required. (The first magazine cassette available is Vol. 1 No. 10; the first disc available is Vol. 3 No. 1.)

MAGAZINE CASSETTE SUBSCRIPTION RATES

6 MONTHS (5 issues) UK £17.00 INC... Overseas £20.00 (No VAT payable)
1 YEAR (10 issues) UK £33.00 INC... Overseas £39.00 (No VAT payable)

MAGAZINE DISC SUBSCRIPTION RATES

6 MONTHS (5 discs) UK £25.50 INC... Overseas £30.00 (No VAT payable)
1 YEAR (10 discs) UK £50.00 INC... Overseas £56.00 (No VAT payable)

CASSETTE TO DISC SUBSCRIPTION TRANSFER

If you are currently subscribing to the BEEBUG magazine cassette and would prefer to receive the remainder of your subscription on disc, it is possible to transfer the subscription. Because of the difference between the cassette and disc prices, there will be an extra £1.70 to pay for each remaining issue of the subscription. Please calculate the amount due and enclose with your order.

ORDERING INFORMATION

Please send your order to the address below and include a sterling cheque. Postage is included in subscription rates but please add 50p for the first item and 30p for each subsequent item when ordering individual discs or cassettes in the UK. Overseas orders please send the same amount to include the extra post but not VAT.
